The term figure refers to any graphical display used to present information or data, including statistical graphs, maps, algorithms, illustrations, computer-generated images, and photographs. Figures may be used to clarify or explain methods, to present evidence and quantitative results, to highlight trends and relationships among data, to clarify complex concepts, or to illustrate items or procedures. Figures should be accurate, clear, and concise. In scientific articles, selection of a particular type of figure depends on the purpose and type of information being displayed. Some of the most common types of figures in biomedical publications are discussed herein. Line graphs have 2 or

Maps are useful to demonstrate relationships or trends that involve location and distance or to illustrate study sampling methods (Example). Maps may be used to demonstrate geographic relationships (eg, spread of a disease). Choropleth maps depict quantitative data (eg, relative frequencies by county, state, country, province, or region), with differences in numerical data, such as rates, shown by shading or colors. Authors should verify map details to avoid misspelled or incorrect names, deleted features, distorted geographic relationships, misplaced or missing cities, and misplaced boundaries.

Photographs and Clinical Imaging

Photographs and other images in biomedical articles are used to display clinical findings, experimental results, or clinical procedures. Such figures include radiographs and those

from other types of medical imaging, photomicrographs, and photographs of patients and biopsy specimens. The availability of digital imaging has provided the ability to enhance images of photographic scientific data, such as clinical images or gel electrophoresis bands. Such digital manipulation may produce misleading or fraudulent images. Some publications require that authors who submit digital images also submit the original gels, while others ask authors to list image adjustments in the paper itself.

Line graphs have 2 or 3 axes with continuous quantitative scales on which data points connected by curves demonstrate the relationship between 2 or more quantitative variables, such as changes over time. Line graphs usually are designed with the dependent variable on the vertical axis (y-axis) and the independent variable on the horizontal axis (x-axis) (Example , Example). Survival plots of time-to-event outcomes, such as from Kaplan-Meier analyses (see Figure in , Study Design and Statistics), display the proportion of individuals, represented on the y-axis as a proportion or percentage, remaining free of or experiencing a specific outcome over time,

Clear display of data or information is the most important aspect of any figure. For figures that display quantitative information, data values may be represented by dots, lines, curves, area, length, or shading, based on the type of graph used. The horizontal scale (x-axis) and the vertical scale (y-axis) indicate the values of the data plotted in a graph. In most graphs, values increase from left to right (on the x-axis) and from bottom to top (on the y-axis). The range of values on the axes should be slightly greater than the range of values being plotted, so that the entire data

Flowcharts demonstrate the sequence of activities, processes, events, operations, or organization of a complex procedure or an interrelated system of components. Flowcharts

are useful to depict study protocol or interventions (Example), to demonstrate participant recruitment and follow-up such as in a randomized controlled trial (CONSORT) (Example , and Figure in , Study Design and Statistics), or to show inclusions and exclusions of samples in other types of studies, such as in meta-analyses of observational studies (MOOSE), meta-analyses of randomized controlled trials (QUOROM), and studies of diagnostic accuracy (STARD). Decision trees are analytical tools used in cost-effectiveness and decision analyses. The

Illustrations may explain physiological mechanisms, describe clinical maneuvers and surgical techniques, and provide orientation to medical imaging. Complex interactions often are easier to convey and understand in an illustration than in text or tables (Example).

Figures Reproduced or Adapted From Other Sources

It is preferable to use original figures rather than those already published. When use of a previously published illustration, photograph, or other figure is determined necessary, written permission to reproduce it must be obtained from the copyright holder (usually the publisher). The original source should be acknowledged in the legend. If the original source in which the illustration has been published is included in the reference list, the reference may be cited in the legend, with the citation number for the reference corresponding to its first appearance in the text, tables, or figures (see , Table Components, Footnotes, and ,

UPDATE: We will discontinue using quotation marks to identify parts of an article, but retain the capitalization; eg, This is discussed in the Methods section (not the “Methods” section). This change was made February 14, 2013. Many journals, including JAMA, use both titles and legends to describe and clarify figures. Others, like the Archives Journals, combine the title and legend underneath the figure. The figure title follows the designation “Figure” numbered consecutively (ie, Figure 1, Figure 2) and does not appear in the figure

itself. Articles that contain a single figure use the designator “Figure” (not “Figure 1”). The title is a

Consent for Identifiable Patients

For photographs or videos in which an individual can be identified (either by himself/herself or by others), the author should obtain and submit a signed statement of informed consent from the identifiable person that grants permission to publish the photograph (in print, online, in video, and all licensed versions, if appropriate). Previously used measures to attempt to conceal the identity of an individual in a photograph, such as placing black bars over the person’s eyes, are not effective and should not be used (see , Ethical and Legal Considerations, Protecting Research Participants' and Patients' Rights in Scientific Publication, Patients' Rights
